Contextualizing Methods Choice in Organizational Research

David A. Buchanan  
*Cranfield University*  
Alan Bryman  
*University of Leicester*

The field of organizational research displays three trends: widening boundaries, a multiparadigmatic profile, and methodological inventiveness. Choice of research methods, shaped by aims, epistemological concerns, and norms of practice, is thus also influenced by organizational, historical, political, ethical, evidential, and personal factors, typically treated as problems to be overcome. This article argues that those factors constitute a system of inevitable influences and that this contextualization of methods choice has three implications. First, it is difficult to argue that methods choice depends exclusively on links to research aims; choice involves a more complex, interdependent set of considerations. Second, it is difficult to view method as merely a technique for snapping reality into focus; choices of method frame the data windows through which phenomena are observed, influencing interpretative schemas and theoretical development. Third, research competence thus involves addressing coherently the organizational, historical, political, ethical, evidential, and personal factors relevant to an investigation.

**Keywords**: research methods; organization politics; research ethics; context; paradigm

Methods out of Context

Choice of method tends to be presented as a step in the research process between setting objectives and commencing fieldwork. Consequently, methods are characterized in terms of finding the appropriate tool in relation to research topic and questions. Partially accurate, this depiction decontextualizes method, providing an incomplete basis for explaining the approach deployed in a particular study. This article aims to demonstrate how choice of method is shaped not only by research aims, norms of practice, and epistemological concerns but also by a combination of organizational, historical, political, ethical, evidential, and personally significant characteristics of the field of research. These factors are often acknowledged as difficulties facing the field researcher but we argue instead that they are naturally occurring and unavoidable influences that must be accommodated in decisions concerning choice of method as they cannot simply be overcome through diligent planning. This perspective locates method as an integral component of a wider, iterative, coherent research system, influencing the social possibilities of data collection as well as the substantive nature of data collected and the nature and direction of theory development. Those organizational, historical, political, ethical, evidential, and personal factors are not just unwelcome distractions. They are core components of the data stream, reflecting generic and specific properties of the research setting, central to the analysis and interpretation of results and to the development of
theoretical and practical outcomes. We thus portray the research process in a less linear man-
ner than is typically depicted in textbooks, arguing that our alternative characterization more
effectively captures the realities of research methods decisions and that this perspective will
be instructive for students and novice researchers.

Our argument has three steps. First, to establish the platform for the argument that follows,
we outline three significant trends in organizational research: the widening boundaries of this
field, its multiparadigmatic profile, and its methodological inventiveness. Second, we con-
sider the range of factors influencing method decisions. Finally, we consider the implications
of this perspective for the theory and practice of organizational research.

**Boundaries, Paradigms, Inventiveness**

This section argues that organizational research has since its inception widened its bound-
aries dramatically, has developed (as have other social sciences) a multiparadigmatic profile,
and has been extraordinarily inventive with regard to the development of data collection meth-
ods. A more restricted domain with a broad epistemological consensus would perhaps display
less methodological creativity and present a narrower range of methods problems and
choices. But the growth in popularity of mixed-methods research has problematized, if not
ruptured, the relationship between epistemology and method, weakening confidence in and
preoccupation with those links (Teddlie & Tashakkori, 2003). Consequently, method is
increasingly located in the context of wider and more fluid intellectual currents, discouraging
rigid adherence to epistemological positions, encouraging a more pragmatic “do whatever
necessary” or “pick and choose” approach to methods choice.

**Widening Boundaries**

The term *organizational behaviour* was coined by Fritz Roethlisberger to suggest the
widening scope of human relations. So in 1957 the Human Relations Group (previously the
Mayo Group) at Harvard Business School was renamed the Organizational Behaviour Group,
which was recognized as a subject at Harvard in 1962 with Roethlisberger (1977) as the first
area head. Research at that time focused on work design, motivation, job satisfaction,
rewards, groups, technology, leadership, and performance. Four decades later, in the intro-
duction to their *Handbook of Organization Studies*, Clegg, Hardy, and Nord (1996) argued
that the traditional label no longer reflected the scope of the subject or captured the work of
those outside business and management with an interest in organizational issues. We now see
research in topics such as aesthetics, bullying, change processes, creativity, cross-cultural
communication, discourse, e-commerce, emotion, empowerment, ethics, fear (and loathing),
feminism, femininity, gender, harassment, innovation, institutions, language, learning organi-
zations, masculinity, narrative, organizational memory, political behaviour, power, psycho-
logical contract, reflexivity, sexuality, storytelling, symbolism, and work-life balance.
Although this caricature of a once narrowly defined field is inevitably unfair (the employee
counseling program at the Hawthorne plant, for example, addressed domestic and emotional
concerns; Roethlisberger & Dickson, 1939), the argument concerning the broadening of
boundaries is valid. It could be argued that our illustrative topic list is incomplete and that the field of organizational research is now unbounded.

Researchers across this field also embrace diverse aims. Some are concerned with establishing covariation, identifying causal links, building models, or testing hypotheses. Others are more preoccupied with rich description, capturing the complex texture of the organizational world as a valuable goal in its own right. For example, Goes and Park (1997) offered a compelling demonstration of the relationships between interorganizational networks and healthcare innovation, using methods (survey and published performance data) that reveal little or nothing of how those networks function or how they trigger and develop innovation processes. In contrast, O’Leary (2003) presented four competing narrative constructions, based on employee accounts from a newspaper company that depicted widely divergent perspectives on organizational life, using methods (participant observation and interviews) that reveal little or nothing of how those constructs and stories might be related to individual satisfaction or motivation, employee behaviors, management-employee relations, or organizational effectiveness. In one case the links are shown but not the underlying mechanisms; in the other, the mechanisms are displayed but what these are connected to is unclear. These remarks are not intended as criticism of either of those contributions but simply to illustrate the implications of contrasting research objectives and their coexistence in this field.

Multiple Paradigms

The field of organizational research is no longer dominated or constrained by positivist (or neopositivist) epistemology and its extended family of primarily quantitative hypothetico-deductive methods (Campbell & Stanley, 1966; Cook & Campbell, 1979; Shadish, Cook, & Campbell, 2001). Relatively few researchers today support the notion of a fixed hierarchy of evidence, with the double-blind randomized controlled trial as the ultimate model of proof (Tranfield, Denyer, & Smart, 2003). Nor is it possible to capture the range of epistemological positions with the distinction between variance and process theories (Langley, 1999; Mohr, 1982). Organizational research displays a variety of positivist, critical, phenomenological, constructivist, interpretative, feminist, and postmodern perspectives. Developing the work of Burrell and Morgan (1979) on paradigms, Deetz (1996, 2000) identified four research orientations based on dimensions of contrast. One dimension is local/emergent versus elite/a priori based on the sources of ideas and concepts, either in dialogue with respondents, or established by the researcher on theoretical grounds. The second is consensus versus dissensus based on relationships between research aims and the dominant social discourse, with the aim either to confirm unity of understanding or to expose conflicts and tensions. These dimensions produce four “analytic ideal types” (Deetz, 1996, p.195), or different ways of engaging in research, although Deetz (1996) observed interplay as researchers are adept at “dodging criticism by co-optation” (p. 119) of other orientations (but it is important to note that adherents to more or less extreme versions of these positions disagree fiercely). A normative (positivist) discourse assumes progressive enlightenment, rationalization and control, with concerns for codification, with establishing covariation and causal relations through hypothesis testing, with cumulative evidence, and with nomothetic laws
(e.g., Hamel, 2000). An interpretative (constructivist, phenomenological) discourse regards sense-making individuals as engaged participants, as cocreators of social structures, using ethnographic and hermeneutic methods to establish local meanings grounded in social and organizational practices (e.g., Fincham, 2002; Huxham & Vangen, 2003). A critical (neo-Marxist) discourse views organizations as sites of political struggle. The research aim is to unmask modes of domination and distorted communication by showing how these are reproduced and to highlight how social practices and institutional structures create and sustain power differences, obscuring alternative perspectives (e.g., Knights & McCabe, 1998).

A dialogic (postmodern, Foucauldian) discourse focuses on the role of language in the constructed and polyvocal nature of social reality. Organizations are viewed as disjointed narratives that fail to establish a coherent reality. Dialogic discourse seeks to expose the pervasive and fluid nature of power relations in contemporary society; to unpack taken-for-granted realities; and to uncover their complexities, lack of shared meaning, and hidden resistances (e.g., Collins & Rainwater, 2003). When publishing, researchers are usually encouraged, implicitly or explicitly, to locate their work on such a map, potentially straddling more than one quadrant.

**Methodological Inventiveness**

The paradigm wars of the 1980s have thus turned to paradigm soup, and organizational research today reflects the paradigm diversity of the social sciences in general. It is not surprising that this epistemological eclecticism has involved the development of novel terminology; innovative research methods; nontraditional forms of evidence; and fresh approaches to conceptualization, analysis, and theory building. Examples of inventiveness in method include the use of organizational stories (Barry & Elmes, 1997; Boje, 1991, 2001; Kolb, 2003; Taylor, 1999); narratives (Czarniawska, 1999; Doolin, 2003; Pentland, 1999); visual, pictorial, and photographic images (Buchanan, 2001; Emmison & Smith, 2000; Harper, 1994, 2000; Meyer, 1991; Stiles, 2004; Suchman, 1995); feature films (Buchanan & Huczynski, 2004; Champoux, 2001; Foreman & Thatchenkery, 1996; Hassard & Holliday, 1998); discourse analyses (Dick, 2004); and collaborative strategies involving respondents as coresearchers and cointerpreters of findings (Denis & Lomas, 2003; Heller, 2004). These innovations are particularly evident in the domain of qualitative and interpretative methods (Prasad & Prasad, 2002). Meyer (1991) observed that a “burst of innovation” and a “new pluralism in methodology” (p. 218) in organization science had not affected data collection methods; that criticism has now been addressed. Traditional preoccupations with representative sampling and statistical generalization have long been complemented by arguments for the value of small-\(n\) studies and for the epistemology of the singular, based on naturalistic (Stake, 1994) and analytical generalization (Buchanan, 1999; Butler, 1997; Dyer & Wilkins, 1991; Eisenhardt, 1989; Mintzberg, 1979a; Mitchell, 1983; Stake, 2000; Tsoukas, 1989; Yin, 2003).

One reason for this paradigmatic diversity and methodological innovation is that this field is a meeting point for numerous disciplines: psychology; social psychology; sociology; economics; public policy; history; anthropology; and the business areas of strategy, finance, marketing, human resources, and operations management. Each of these disciplines, and related subdisciplines, brings its own distinct perspectives and traditions. Furthermore, there is a growing acceptance, if not endorsement, of studies that combine quantitative and qualitative research. Such a mixed-methods approach potentially provides
opportunities for greater insight than can be achieved by one approach alone (e.g., Currall & Towler, 2003; Yauch & Steudel, 2003). This development further contributes to the sense of paradigm soup as researchers using such approaches tend to set aside the epistemological and ontological divisions that previously divided scholars and because this questions the appropriateness of traditional research quality criteria (such as validity and reliability) as well as qualitative alternatives (Lincoln & Guba, 1985). Consequently, the field is fragmented, with no central core of traditions, frameworks, and concepts, no unified theoretical or practical proposal.

Trends in the field of organizational research thus include a widening of boundaries, adoption of a range of orientations (epistemologies), and methodological innovation. The following section locates method in the context of a number of other properties of the organizational research field, which can systematically and unavoidably influence choice of method.

Field Properties

Although personal experience sits at the bottom of the hierarchy of evidence, to be treated with caution if not discarded, it is personal research experience that informs this discussion. We consider features, challenges, and tensions that have colored, indeed determined, our own methodological decisions but that tend to be regarded as problems in most accounts, not considered as legitimate influences on those decisions. In particular, we consider the organizational, historical, political, ethical, and evidential properties of the research field and the resources or personal properties of the researcher. Figure 1 summarizes this argument, illustrating the broad system of influences on choice of organizational research methods, beyond traditional concerns with the link to research topic, question, and objectives. In practice, this system of influences has multiple interrelationships, and the arrows for presentational purposes indicate only the primary influences on methods choice.

Organizational Properties

The logistics of fieldwork will always be more or less significantly influenced by properties of the focal organization such as size, location (single or multiple sites), and whether it is a commercial organization or a professional bureaucracy (Mintzberg, 1979b). Choice of method can also be heavily contingent on the stability of the research site or sites. Predetermined and inflexible methods are less appropriate (perhaps inappropriate) where the organizational context is changing. But one significant contemporary feature of medium- and large-sized organizations concerns the scale and frequency of role and structure change. For example, a tracking study of large British firms found that they experienced major changes on average every 3 years and that a third engaged in large-scale reorganizations every year (Whittington & Mayer, 2002). Although such studies focus on the organizational repercussions (e.g., on the need to develop management skills in adaptive reorganization), this has implications for research method. For example, the simple question, “What is your job title?” is often met with a bemused smile, as many managers have portfolios of responsibilities that change frequently (Buchanan, 2003). Establishing a sampling frame or a list of key informants or constructing an organization chart can be

committee positions
problematic. On several occasions, in different settings, we have returned within a matter of weeks to reinterview a respondent to find that they have assumed another role or set of roles and that our line of questioning is no longer relevant. Growth in outsourcing of key services and the development of network forms of interorganizational collaboration (e.g., in healthcare) means that members of partner organizations might be unsure which organization or project they are being questioned about. Taking static measurements to establish covariation is of limited relevance and the significance of process theories, based on contextualized event sequence analysis, is enhanced (Pettigrew, Woodman, & Cameron, 2001; Poole, Van de Ven, Dooley, & Holmes, 2000). Depending on the research topic, the flux and patterns of change become substantive data observations and the role of the researcher may be to “catch reality in flight” (Pettigrew, 1990, p. 268). In these kinds of rapidly changing organizational settings (Buchanan, 2000; Eisenhardt & Bourgeois, 1988), research methods must be regularly adjusted according to circumstances in a flexible manner as initial plans become inappropriate and as fresh lines of inquiry become apparent. As discussed below, such flexibility is problematic when ethical guidelines require researchers to detail methods in advance and to adhere rigidly to those plans.

**Historical Properties**

The history of a research field conditions contemporary method decisions by providing an experience and evidence base, benchmarks, departure points, and traditions. Consequently, the ghosts of the Hawthorne studies continue to haunt researchers in the 21st century, having made durable contributions to research agendas, methodology, and terminology. In the natural and biomedical sciences, new research builds on previous work, rendering it obsolete. Organizational research is rarely cumulative in this respect and researchers ignore at their peril the historical record, the concepts and evidence from long-running research streams, and past contributions in their field. For example, although research into leadership traits was abandoned in the 1950s following contradictory and inconclusive findings, similar studies still surface in popular, academic, and professional literature (Charm & Colvin, 1999; Department of Health, 2002; Kamp, 1999; Leigh & Walters, 1998). Organizational researchers may thus be advised to allow past experience, frameworks, conceptualizations, and findings to influence contemporary choices of research focus and appropriate methods.

**Political Properties**

As organizations are political systems (Mintzberg, 1983; Pfeffer, 1992), it is difficult for researchers to respect conventional norms of observer neutrality by avoiding entanglement in power and political issues. Researchers are routinely engaged in political actions in at least four ways: when negotiating research objectives, when obtaining permissions to access respondents, aligning with stakeholder groups, and when attempting to publish findings.

*Negotiated objectives.* Researchers often find themselves negotiating their objectives with the gatekeepers who can sanction or block their work (Korczynski, 2004). A gatekeeper is anyone in a position to decide whether a research project can proceed at a given site. From a methods perspective, this can be problematic in at least two respects. First, in many organizational settings the field researcher may be faced not with a single gatekeeper
but with many individuals who can either allow or deny research access. Second, the researcher may often (not always) have choice with regard to which gatekeepers to approach, choosing (for example) the most senior or the one with whom they have the closest relationship; it may be politically unwise to approach more than one gatekeeper simultaneously. However, gatekeepers can make their consent contingent, and the spirit of free inquiry is jeopardized when certain themes and topics are discouraged and others welcomed. One solution involves overtly describing a study in innocuous terms (a study of interpersonal relations and team dynamics) while wording data collection instruments to incorporate related themes (age, race, and sex discrimination in promotions), tailoring observations and document collection accordingly. This approach raises ethical concerns relating to appropriate degrees of openness and honesty on the part of the researcher and the degree to which gatekeepers and respondents may be misled with regard to the researcher’s intentions, implying that fully informed consent may not have been given. For example, in their study of management perceptions of organization politics, Madison, Allen, Porter, Renwick, and Mayes (1980, p. 83) argued that the topic was “too sensitive for use in direct investigations” and that researchers should cloak the term politics with an appropriate euphemism (managers in this instance were asked to talk about their “total experience” of work with several employers). In our experience, funding can be linked to the researcher’s willingness to address specific themes, questions, and problems in a particular manner. Failure to comply with such expectations has predictable implications for the success of research grant submissions, which may be magnified when funding bodies insist that organizational research access is secured before financial support can be released.

**Layered permissions.** Organizational researchers can rarely approach respondents directly with requests to participate in their studies. Permission typically has to be obtained first from a senior management gatekeeper, who may often refer such requests to other senior colleagues and in some instances to a management committee or board. In turn, once a general warrant to proceed has been granted, unit or department managers may then have to be approached with further requests to access “their” staff in a particular manner. Individual respondents can, of course, then refuse to collaborate despite that cascade of management concessions. This layering of permissions has at least two consequences for method. First, this can delay the start of data collection; second, this can compromise research objectives and methods. Permission may be constrained in terms of the topics that can be investigated, the questions that can be asked, the materials that can be collated, and the timing and manner in which data collection is allowed to unfold.

**Partisan conclusions.** One of the dilemmas of organizational research concerns the extent to which researchers align (or are encouraged by circumstances to align) their agendas with the interests of specific stakeholder groups. Support for managerial agendas—implicit or explicit, direct or indirect—attracts accusations of partisanship captured by the phrase servants of power. As management permission is typically a prerequisite for organizational access, it is often difficult to avoid linking research aims explicitly to managerial interests in a way that could potentially damage the interests of other stakeholder groups—for example, assessing process redesign options that would reduce staffing, skill, and payment levels.
Researchers are often asked to report their findings to those who granted access as a form of quid pro quo for providing documentation and allowing staff to be interviewed, complete questionnaires, or attend focus groups, for example. Such reporting implies a tacit acceptance of managerially defined themes and problems. The consequences of failing to meet gatekeeper expectations in this respect can be damaging to the researcher’s local reputation, may restrict publication of findings, occasionally leads to the censorship of reports, and can close that research site to other investigators. For example, O’Connor (1995) studied written accounts of change authored by internal organization development groups in a high-technology manufacturing company. The texts praised the efforts of the organization development function, whose members had authored the accounts in 25 to 30–page case studies, presenting the organization development function and key individuals as pivotal in change initiation and implementation. In her conclusions, however, O’Connor observed how involvement in key decisions was limited to a small group of key managers, how disagreement was treated as resistance and lack of understanding rather than as involvement, and how change narratives revolved around a heroic figure with adversaries. The host organization did not welcome O’Connor’s interpretations. Her gatekeeper denied her account, described it as shocking, outrageous, and unacceptable, and never met with her again. Such a candid account is unusual but almost certainly reflects a relatively common organizational field research experience.

**Politics of publishing.** There is an additional dimension to the presumed link between research questions and methods that concerns the wider politics of getting one’s findings into print. Essentially, this issue involves the epistemological privileging of certain forms of knowledge by those in editorial positions. Thus, Huy (2001) established his credentials as a normative managerialist commentator in a *Harvard Business Review* article but identified himself as an interpretative sociologist in *Administrative Science Quarterly* (Huy, 2002). Knights and McCabe (1998) adopted a critical labor process perspective in *Human Relations* but Knights (2002) established a postmodern identity in *Organization*. Such credentialing is typically accomplished subtly through a combination of language use and appropriate referencing. To expose more clearly the artifice behind such stylistic manipulations, some authors have deliberately resorted to publishing their findings using several different “voices” (e.g., Collins & Rainwater, 2003; Rhodes, 2001). Sutton (1997) argued that he had to downplay the significance of his qualitative data to get his papers published in journals that prioritize quantitative research, and he became a closet qualitative researcher “because some editors, reviewers, and journals remain unfairly biased against qualitative research” (p. 99). The quality of authors’ arguments about the appropriateness of their research methods should resolve such disputes, were those decisions based just on links to aims. However, Sutton’s experience suggests that bias against one orientation or another is sometimes too strong and that researchers are disadvantaged when editors and reviewers discount claims for the appropriateness of particular methods regardless of the cogency of the supporting case.

Further light on this issue was shed by Herman and Egri (2002), who described the background to their research on environmental leadership (Egri & Herman, 2000). In a revealing discussion about their research planning, they noted that one of the main reasons they chose to combine their qualitative approach with a survey was that they “understood that qualitative
research alone would not satisfy many mainstream academics” (Herman & Egri, 2002, p. 132). If methods flowed primarily from research questions, researchers would not feel compelled to employ techniques they would otherwise prefer not to use. It is apparent that the politics of publishing pull investigators in directions that may be politically correct but with which they may not always feel comfortable; these observations further undermine the textbook connection between research questions and methods.

The political dimensions of organizational field research mean that claims to observer neutrality, as across the social sciences, are hollow. Researchers are often motivated by a desire to challenge management practices, to trigger intervention, and to effect change. Why investigate power if not to identify ways of addressing its consequences or to reduce power inequalities? Why study quality of working life or sexual harassment unless one wishes to improve the one and overcome the latter? Stakeholder alignment has fundamental if rarely reported implications for method concerning, for example, respondent selection, modes of observation, and lines of questioning, with respect to issues that are included and topics that are considered beyond the boundaries of the study.

**Ethical Properties**

Organizational research has attracted an increasing level of ethical scrutiny. A number of bodies (Academy of Management, British Sociological Association, British Psychological Society, European Market Research Association, Social Research Association) have long-standing research ethics codes, and there is little or no evidence to suggest that those codes are even occasionally contravened. However, in Britain, the Department of Health (2001a, 2001b, 2001c, 2005) Research Governance Framework applies the standards for biomedical research (drug trials, new treatments) to organizational research in health and social care even when patients or clients are not implicated. This involves a protracted application process policed by local and multisite research ethics committees concerned primarily with issues of informed consent, right of withdrawal, and respondent anonymity. However, policy guidelines clearly invite ethics review committees to challenge (and reject) methods choices, stating that “research which is not of sufficient quality to contribute something useful to existing knowledge is unethical” (Department of Health, 2005, p. 13). In addition to traditional concerns, therefore, committees also consider aspects of method where, in their judgment, inappropriate choices may have been made. In our recent experience, an ethics review panel rejected a proposal for a study of management processes where the main data collection methods were scrutiny of documentation and observation of management committee meetings. Some members of those management committees, the panel argued, could come under undue social pressure to consent to observation, which thus rendered the method unethical. In two other separate instances involving qualitative inductive multimethod case studies of service improvement initiatives, ethics committees challenged proposals for lacking precision with regard to sampling and questioning strategies, unimpressed by arguments concerning the need to adjust methods in a flexible manner during fieldwork in the light of emerging themes, findings, and organizational changes.

The open-ended nature of some qualitative inquiry can thus surface ethical concerns. Some research modes, such as grounded theory, discourage the specification of research
questions in advance of data collection, privileging issues emerging during the investigation (Locke, 2001). In America, institutional review boards make life difficult for qualitative researchers who advocate flexible methods so that new questions can emerge and be pursued effectively. This has led to clashes between researchers and institutional review boards, which often employ biomedical research standards, prohibiting flexible methods on ethical grounds because the investigator does not know exactly how the research will be done (Lincoln & Tierney, 2004). Lynn (2004) reported the case of an institutional review board that successfully argued that a hospital quality-improvement project, led by managers but leading to publication of the lessons derived, constituted research activity and should thus have been subject to prior ethical review (a judgment which, if applied consistently, would in Lynn’s view present insurmountable barriers to quality-improvement projects). Moreover, the growing tendency, following the Belmont Report, for matters of research design, quality, and ethics effectively to become fused magnifies the problem when biomedical criteria for research quality and ethics are applied (Sieber, 2004). These trends parallel the consequences of the British Department of Health Research Governance Framework (Truman, 2003), whereas the implications of the Belmont rules are much broader. Indeed, there are calls in Britain for the light-touch approach to ethical vetting in nonhealth fields to become more rigorous (Kent, Williamson, Goodenough, & Ashcroft, 2002). The notion that research methods depend only on research questions is untenable when considering the open-ended nature of qualitative research and the ethical context in which many researchers ply their trade, requiring them to mould methods to sometimes inappropriate criteria.

The increased intensity of ethical scrutiny is perhaps not surprising. There has been growth in public concern with the process and outcomes of all types of scientific enquiry, and researchers must be able clearly to justify their approach. Researchers must also comply with legislation concerning, for example, discrimination, privacy, and data protection to protect themselves as well as informants. Some social and organizational research involves vulnerable respondents who deserve protection from researchers who may cause unwitting harm. Some social and organizational research focuses on controversial and sensitive issues about which some respondents may be reluctant to speak openly and where researchers must avoid exerting pressure on individuals to submit to a project’s requirements.

Ethical scrutiny generates other challenges for method. It may not always be practicable to gain prior consent from every respondent likely to be involved in a study in which some form of observation will be used, thus breaching the principle of right to withdraw. Some researchers may be concerned about contamination by presensitizing respondents with knowledge of the research aims; this can be avoided by misleading respondents, breaching the principle of informed consent. In publishing, a researcher may be required to omit information that, although relevant to the development of an explanation of the phenomenon under investigation, would disclose individual or organizational identity, breaching the principle of anonymity. We were recently asked to delete discussion of a conference that had contributed to an organizational change process; participants had reacted unfavorably to the style and content of some of the presentations. However, several delegates had been prompted by that experience to develop their own approach to the issues in hand, thus securing their commitment to the change agenda. Discussion of this critical incident was proscribed because it would “unnecessarily embarrass the conference organizers, who had already learned from that mistake.”
The spotlight of ethical scrutiny is currently focused on the proposal stage. Should the research process as a whole become subject to ethical monitoring, as has been informally suggested, field researchers can face even more constraints with regard to choice of appropriate and acceptable data-collection methods.

**Evidential Properties**

Organizational researchers often have to consider how and by whom their findings will be used before making methods choices so relevant audiences will perceive their approach as having been appropriate. Researchers thus have to take into account the potentially conflicting interests and expectations of their academic, managerial, and research participant audiences. Academic colleagues expect new knowledge and theoretical insight. Organization managers anticipate practical recommendations. Research participants typically wish to know that their contributions have been interpreted and used in an appropriate manner and are presented anonymously. The process that leads from problem definition to data collection, evidence, conclusions, prescription, and subsequent changes in organization practice might appear to be linear but is problematic. The relationships between evidence and practice in most fields (including medicine, where “evidence-based medicine” is now mandatory) are complex (Fitzgerald, Ferlie, Wood, & Hawkins, 2002), and the external validity of organizational research remains contentious. Qualitative researchers often have a limited interest in statistical generalization, emphasizing instead analytical (link to theory) and naturalistic (link to experience) generalization. Findings generated in one setting (acute medical care) may not generalize to others (bespoke furniture manufacture). Researchers must judge the scope conditions for their findings or derive moderatum generalizations, indicating that aspects of a situation or context can be viewed as “instances of a broader recognizable set of features” (Williams, 2000, p.215). Feeding back acceptable findings in the context of a professional organization (Brock, Powell, & Hinings, 1999; Mintzberg, 1979b) such as healthcare presents challenges not commonly faced by researchers in commercial settings. Doctors and engineers, for example, schooled in the norms of biomedical and natural science research practice, are understandably suspicious of research findings based on methods that do not appear to follow those familiar protocols. Thus, evidence has to meet a receptive audience whose members have adequate organizational authority for findings to transfer smoothly into practice. That combination of factors is rare. It may even be the case that the researcher has to offer to conduct an enquiry specifically in a manner that gatekeepers regard as credible. For example, to secure access to a General Motors factory, Milkman (1997) agreed to conduct a survey that would provide “hard quantitative data,” even though her research required a qualitative approach.

Research evidence rarely reveals clear causal links. For all but the most closely bounded topics, the field is multivariate and multilayered. For example, does total quality management improve organizational effectiveness? The main terms in this question are difficult to define with precision—they mean different things in different contexts and to different stakeholders—and the number of interacting factors involved over time at various levels of analysis (individual, team, business unit, organization, external context) defies simplistic attempts at theorizing (Iles & Sutherland, 2001; Øvretveit & Gustafson, 2002). Establishing cause and effect across complex, iterative, and multidimensional processes
over time is challenging. Several commentators have turned to process theories to handle such phenomena (Dawson, 2003; Langley, 1999; Pettigrew, 1985; Van de Ven & Poole, 2002). Process theories tend to adopt a narrative form and to focus on local causality rather than seek to identify universal laws linking dependent and independent variables. An additional complication is that different stakeholders hold contrasting views of the nature, definition, and significance of organizational problems. However, audiences for research findings are often interested mainly in the question “What works?” Researchers who can answer this question may find that their enterprise shares some of the attributes of the work of management consultants but without the financial rewards. The respective roles of researchers and consultants are more closely intertwined than is often acknowledged. Researchers interested in, for example, total quality management or business process re-engineering can argue that they are studying novel organizational forms, but they are also studying the nature and implications of the commercial products of management consulting firms. The findings from such studies may be used both by host organizations and consulting firms to influence organizational change processes.

Decisions about method may thus have to consider the nature of the evidence ultimately required to inform practice and also to assess the acceptability of different forms and sources of evidence to specific audiences responsible for implementing recommendations.

Personal Properties

Researchers commonly study topics in which they have a personal interest, using methods in which they are trained and competent, and with which they feel comfortable. Some researchers enjoy in-depth, face-to-face encounters and the challenge of identifying pattern and order in qualitative data; others find satisfaction at a computer screen, discovering associations in quantitative data sets. A researcher’s training and skills can thus influence both choice of research topic and how it is investigated. Novice researchers are typically instructed not to allow personal preference and bias to intrude on “technical” decisions concerning research methods. Should researchers be encouraged to experience guilt with respect to personal beliefs and passions, with respect to the skills that they have acquired, practiced, and honed? As many commentators have advocated, reflexivity should be encouraged in making and in reporting decisions concerning research methods.

Departing from the convention that relationships with research participants contaminate data, Dutton and Dukerich (2006) argued that the researcher’s social networks and interpersonal skills (relational practices) are critical to designing and sustaining interesting organizational research. Although the contribution of friends and acquaintances with regard to accessing organizations as research sites and gathering relevant inside information may be widely appreciated, these issues are rarely recognized in published accounts as factors influencing research design (Buchanan, Boddy, & McCalman, 1988; Dutton & Dukerich, 2006).

Package Deals and the Unseen: Implications for Method

This article began with the argument that the field of organizational research displays at least three significant trends. The first concerns widening the scope of the agenda and embrac-
ing a growing range of themes, issues, problems, and settings. The second theme, common
across the social sciences, concerns an eclectic, multiparadigmatic approach that has con-
tributed to a weakening of the traditional dominance (but not necessarily the influence) of
positivist orientations. Although blurred at the margins, those competing orientations gener-
ate intense debate. Consequently, the field is fragmented, with little or no consensus around
concepts, frameworks, theories, or practical propositions. A third trend concerns the creative
approach to method in this field, which now deploys a diverse array of data collection meth-
ods, with more novel techniques standing alongside and often complementing established
approaches. We then sought to demonstrate that choice of research method is shaped not only
by technical and theoretical considerations related to the research topic, objectives, and norms
of practice but also by a number of other characteristics of organizational field research:

- attributes of the organizational research setting or context,
- the research tradition or history relevant to a particular study,
- the inevitable politicization of the organizational researcher’s role,
- constraints imposed by a growing concern with research ethics,
- theoretical and audience-related issues in translating evidence into practice, and
- personal preferences and biases with regard to choice of method.

These attributes of organizational research have been widely acknowledged but they are
typically represented as problems or difficulties, interfering with choice of method and to
be avoided through careful planning. However, as Figure 1 illustrates, those factors, taken
together, constitute instead an interrelated system of inevitable influences on research
methods choices. Contextualizing methods choice in this web of influence has at least three
implications. First, it is difficult to sustain a model of the researcher as neutral observer.
Even the selection of an underpinning paradigm is a politically inspired act, not merely an
intellectually informed choice because this can involve an implicit alignment with particu-
lar stakeholder interests, overlooking or marginalizing issues that may be more important
to others. Neutrality is often further compromised in feeding back to gatekeepers reports of
research findings, conclusions, and practical recommendations as politically incorrect con-
clusions may be omitted. Researchers claiming neutral status are often pursuing agendas
that are implicitly aligned with partisan agendas. The concept of researcher as detached and
disinterested has already been widely discredited (Van de Ven & Poole, 2002).

Second, it is difficult to sustain a model of the research process in which method relies
solely on links to objectives, with the advantages and limitations of one approach weighed
objectively against others. We have sought to show that method choices is a multicriteria deci-
sion that involves a more complex, interrelated, and iterative series of considerations. Method
in this perspective is part of a package deal, an integral component of a comprehensive research
system where, in the pursuit of particular aims in a given setting, theoretical, epistemological,
organizational, historical, political, ethical, evidential, and personal factors are combined in a
coherent manner. Choice of method is not a stand-alone decision reached at an early stage in
the research process but evolves as a project unfolds, as the researcher’s understanding of the
issues and also of the organizational research setting develops. The widely espoused view, rein-
forced in methods texts and elsewhere, that the research process (sampling, data collection
method, analysis) flows logically and inexorably from research questions, is an oversimplifi-
cation when this range of influences on an investigation is considered (Bryman & Bell, 2003).
It is not surprising that, when Grunow (1995) conducted a content analysis of organization studies articles, he found that only 21% discussed the relationship between the research topic or problem and the methods employed in the investigation.

Third, it is difficult to sustain a concept of method as neutral technique for bringing reality into focus. Shaped by a comprehensive web of influences, decisions concerning method frame the data windows through which organizational phenomena are observed. Methods choices determine the unseen as well as the documented, thus linking organizational, historical, political, ethical, evidential, and personal factors with the development of both theoretical and practical conclusions. Consequently, those factors can be considered as data rather than as features of the research setting of problematic concern. Advocates of reflexivity (Alvesson & Sköldberg, 2000; Woolgar, 1988) have advised openness and honesty with regard to the position and identity of the researcher, accompanied by critical self-appraisal. The argument here suggests that reflexive appraisal should be extended to incorporate a discussion of the sweep of factors influencing methods choices for a given project because these in turn both influence and contribute to the evidence base on which conclusions are constructed.

It is thus important to understand more fully, and to articulate more openly, the basis of research methods choices. The factors affecting those choices could perhaps be more widely reported to support method training by providing a widely informed overview of the nature of the craft and to promote productive dialogue across a research community that seems to be increasingly fragmented by differences in orientation. Despite the web of constraints and influences, the design of organizational research work and the choice of data collection methods remain in part a creative process. This complex package of issues can be combined and configured in a variety of different ways. It is important, therefore, to recognize not only the technical skills and knowledge of the researcher but also the role of personal interests, preferences, biases, prejudices, and creativity.

Competence in research method has traditionally, and narrowly, been expressed in terms of selecting methods consistent with research topic and objectives while avoiding or resolving those annoying practical fieldwork problems. We conclude that competence in method must now also encompass the ability to address, systematically and coherently, the organizational, historical, political, ethical, evidential, and personal influences identified in this paper.
