# Session I I. Platform revolution

Natalia Milovantseva, PhD, April 27, 2019

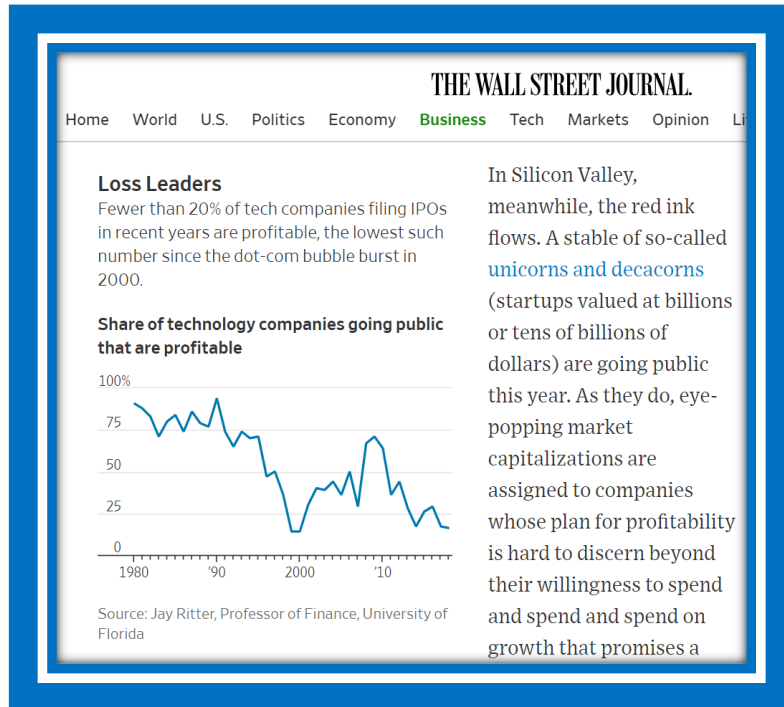

# Follow-up: Literature on digital economy

## CURSORY SEARCH

Google Scholar search results for "цифровая экономика россия". The search bar contains the text "цифровая экономика россия". The results show "Articles" with "About 22,100 results (0.07 sec)". The left sidebar includes filters for "Any time", "Since 2019", "Since 2018", "Since 2015", and "Custom range...". The "Sort by" options are "relevance" and "date". There are checkboxes for "include patents", "include citations", and "Create alert". The first article is titled "Осмысление цифровой экономики" by И.Ю. Юдина, published in 2016. The second article is "Формирование цифровой экономики в России: сущность, особенности, техническая нормализация, проблемы развития" by А.В. Бабкин, Д.Д. Буржалыева, Д.Г. Костень, published in 2017. The third article is "Цифровая экономика: особенности и тенденции развития" by Б. Панышин, published in 2016.

Google Scholar search results for "digital economy". The search bar contains the text "digital economy". The results show "Articles" with "About 35,600 results (0.03 sec)". The left sidebar includes filters for "Any time", "Since 2019", "Since 2018", "Since 2015", and "Custom range...". The "Sort by" options are "relevance" and "date". There are checkboxes for "include patents", "include citations", and "Create alert". The first article is "The Internet trap: How the digital economy builds monopolies and undermines democracy" by M. Hindman, published in 2018. The second article is "Profiting from innovation in the digital economy: Enabling technologies, standards, and licensing models in the wireless world" by D.J. Teece, published in 2018. The third article is "The value-capture problem for innovators in the digital economy" published in 2020. The fourth article is "The Model for Meeting Digital Economy Needs for Higher Education Programs" by EV Bolgova, GN Grodskaya, MV Kurnikova, published in 2020.

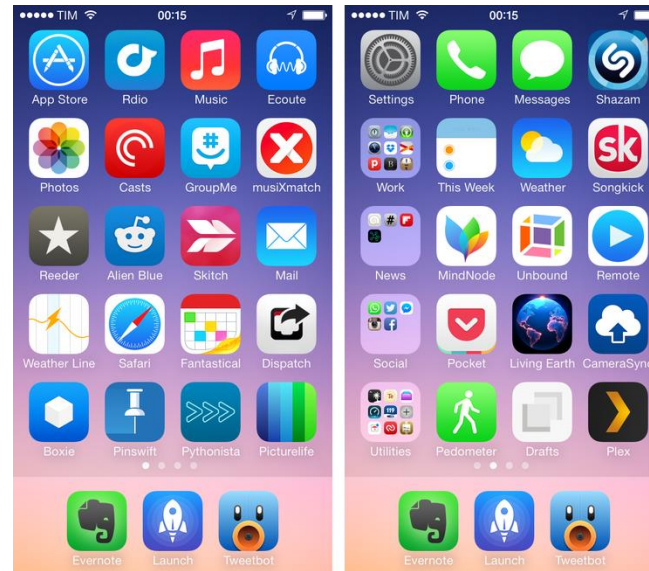

# Follow-up: Why investors don't care if tech companies don't make money

“Despite everything written about short-termism, we’re seeing that as long as these companies have a compelling growth story, investors are actually telling them to not focus on short-term performance.”

*Jay Ritter, University of Florida*

# Digital goods' complements: A case of iPhone

Apple's experiment with third-party apps is an example of data-driven decision-making

Benefits of digital complements to a physical product: The value of the physical product (iPhone) increases as the number of digital complements (iPhone apps) increases.

# Complements and network effects

**Product 1**

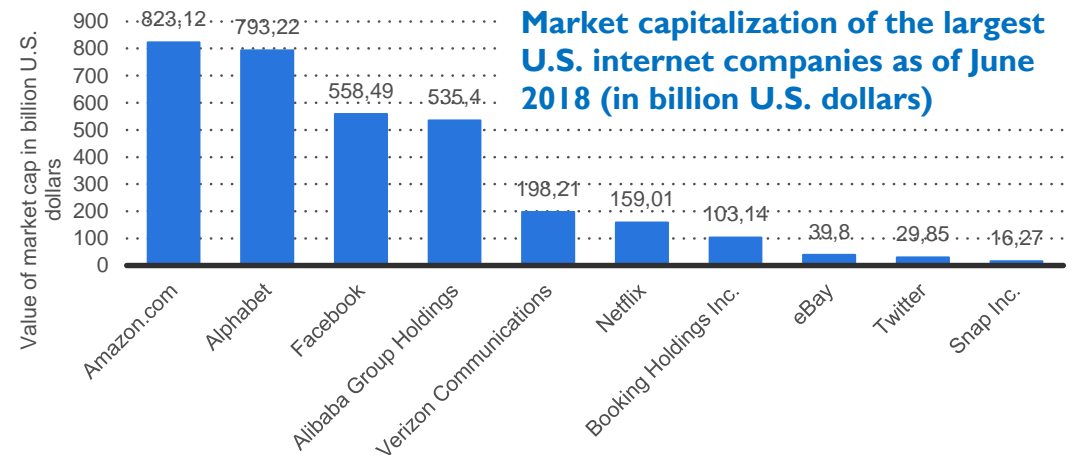

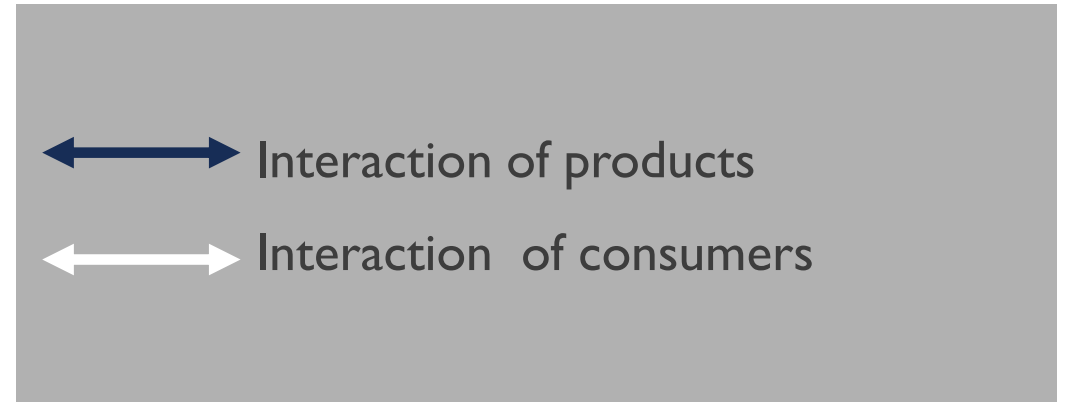

**Product 2**

**ORDINARY  
PRODUCT**

**COMPLEMENTARY  
PRODUCTS**

**NETWORK EFFECT  
PRODUCT**

**TWO-SIDED NETWORK  
PRODUCTS**

## Implications of free, perfect and instant

- In the economy of physical products:
  - Atoms cost money, have potential for quality problems, and take time to make and deliver

Can you think of examples of how these properties – free, perfect and instant – are **TRANSFORMATIONAL** in the economy of ordinary (not digital) goods?

# Implications of free, perfect and instant

- Properties that distinguish digital goods from physical goods:
  - Free - once something is digitized, it's free to make an additional copy of it
  - Perfect - unlike a photocopy of a photocopy, the quality of digital goods doesn't deteriorate with successive copies
  - Instant - the copy is made almost instantly and can be distributed almost instantly
- Interaction effect
  - In a combination, free, perfect and instant worth more than each of them separately
  - It is hard to compete against companies that use a combination of free, perfect and instant
- Digital businesses scale rapidly and compete aggressively with traditional firms that make, own, rent, or use physical goods
  - Even if fixed cost of production are the same, the overall cost advantage of digital would be significant because the marginal cost of *making and distributing additional copies is low*

# Why \$0.00 is the future of business

Video By Chris Anderson, "Free: The Future of a Radical Price" (3:18)  
<https://www.youtube.com/watch?v=RZkeCIW75CU>

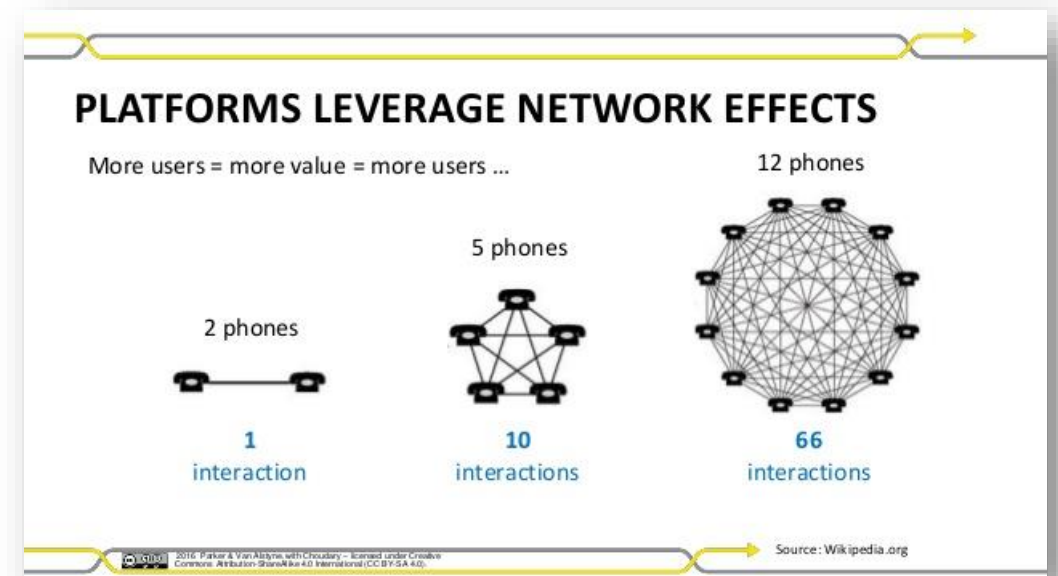

## Benefits from an open platform for digital complements to a physical product

- The number of digital complements increases much more rapidly because the physical product benefits from two-sided network effects, with positive feedback between the number of physical product owners and the number of digital complement developers.
- The number of digital complements increases at much lower cost. These outside digital complement developers are providing free work to the platform because it is in their own interests to do so.

# Platforms

- Platform is a digital environment characterized by *near-zero marginal cost* of access, reproduction, and distribution
  - Marginal cost: the cost of producing or distributing one more item
- A digital platform aggregates supply and demand by connecting users who may be using the same product or complementary products
- Platforms can be built on top of each other
  - The World Wide Web is a platform built on top of the original Internet information transfer protocols
  - The Internet is a platform of platforms

# Types of platforms

- Platforms connect:
  - one category of users - one-sided platforms (example: WhatsApp, Dropbox)
  - two categories of users - two-sided platforms (example: Lyft, Uber)
  - three or more categories of users - n-sided platforms (example: the Android system)
- Curation - encouraging other content that adds value and discouraging content that isn't as valuable

## Example: Apple's two-sided iTunes platform

- App developers make their offering available to more consumers. The bigger the community of consumers, the more value developers can derive.
- Consumers get access to more apps. The more apps there are, the greater the benefit they get from owning the iPhone.
- The platform owner (Apple) sees its physical product gain value and can sell more products and charge a higher price.

# Platform architecture

- Curation is an essential element of optimizing a platform to maximize the value it generates
- Platform architecture: issuing a strict set of guidelines that participants have to meet
- If the added participants or their products are low quality or have negative effects on the community, the network effects of growth can hurt the business
- Balance: creating a larger network faster // creating a higher-quality network slower
- Platform owners typically run experiments to gather data to inform their decisions because trade-off between quantity and quality not obvious
- Mind–machine balance
  - machine side of the balance: automated filters and abuse-reporting systems to detect existing objectionable content or remove participants who violate the terms of service
  - mind side of the balance: fundamental decisions about *curation* belong on the

# Early adopters

- Network effects are great for networks that have reached critical mass or are larger than their competitors
- But, starting a new network can be hard **because the first customers won't see the benefits of the network until it grows**

## Example

- Stripe built a platform that attracted **two groups** of participants: **merchants** who want to get paid, and **financial institutions** involved in delivering payments to merchants.
- They used a strategy employed by the networked multiplayer online games.
